Acne: more than skin deep

J Ayer, N Burrows

Acne is one of the most prevalent skin conditions affecting teenagers. It is a disease of the pilosebaceous unit. Blockage of sebaceous glands and colonisation with *Propionobacterium acnes* leads to acne. Grading the severity of acne helps to determine the appropriate treatment. Treatment of acne should be started as early as possible to minimise the risk of scarring and adverse psychological effects. It should be tailored to the individual patient, the type of acne, its severity, the patient’s ability to use the treatment, and the psychological state. Topical agents are the mainstay for treatment of mild acne. Moderate acne is treated with oral antibiotics. Resistance to antibiotics may be reduced by subsequent use of non-antibiotic topical medications. Severe acne is treated with isotretinoin, and this can lead to permanent remission. With better education and care given by medical profession, acne treatment could be significantly improved.

Acne is one of the most prevalent skin conditions, affecting more than 85% of teenagers. It typically starts at puberty and resolves slowly as the person reaches 20, although some people continue to have acne into their 40s and 50s. It is seldom life threatening and is often dismissed as a self limiting condition. Little attention is given to it in either undergraduate or postgraduate education. Despite its apparent cosmetic nature, its effects can go far deeper than the surface of the skin, and can place a heavy emotional and psychological burden on patients that may be far worse than the physical impact. The change in the skin’s appearance may give rise to a changed body image that in turn is known to lead to anger, fear, shame, anxiety, depression, embarrassment, and bullying and stigmatisation within peer groups. Lack of confidence, social withdrawal, feelings of insecurity and inferiority, limited employment opportunities, functional and interpersonal difficulties at work, and suicidal tendencies have also been reported and attributed to the effects of acne. The reduction in quality of life has been estimated to be as great as that associated with epilepsy, asthma, diabetes, or arthritis.

**AETIOPATHOGENESIS**

Acne is a multifactorial disease: genetic factors, stress, androgens, and excess sweating all influence its development and/or severity. Corticosteroids, oral contraceptives, iodides, bromides, lithium, and chemicals such as dioxin are known to induce acne eruptions, as are endocrine disorders such as Cushing’s syndrome and polycystic ovary syndrome. It is often found that acne is worse in current smokers, but despite popular myth, diet, lack of exercise, lack of hygiene, greasy hair hanging over the face, and masturbation do not have any effect.

Acne is a disease of the pilosebaceous units in the skin. A changed keratinisation pattern in the hair follicle leads to blockage of sebaceous secretion. It is probable that hyperresponsiveness to the stimulation of sebocytes and follicular keratinocytes by androgens leads to the hyperplasia of sebaceous glands and seborrhea that characterise acne. The enlarged follicular lumen attributable to inspissated keratin and lipid debris forms a closed comedone (whitehead). When the follicle has a portal of entry at the skin, the semisolid mass protrudes forming a plug, producing an open comedone (blackhead).

*Propionobacterium acnes* colonises the follicular duct and proliferates, breaking down triglycerides, irritants that probably contribute to the development of inflammation. When the follicular epithelium is invaded by lymphocytes it ruptures, releasing sebum, micro-organisms, and keratin into the dermis. Neutrophils, lymphocytes, and foreign body giant cells accumulate and produce the erythematous papules, pustules, and nodular swelling characteristic of inflammatory acne.

**CLINICAL FEATURES**

The clinical features of acne are a cluster of signs related to distended, inflamed, or scarred pilosebaceous units. Lesional polymorphism is the main feature, and is most commonly seen on the face, back, and the chest. Seborrhea is the most frequently occurring feature. Distended pilosebaceous units can take the form of open or closed comedones, and the types of inflamed lesions exhibited are pustules, papules, nodules, and cysts. In more severe cases, multiple inflammatory papules and nodules fuse to form draining sinuses, which lead to chronic scarring and, rarely, malignant changes. Post-inflammatory lesions may also occur and are represented by macular pigmentation and scars (hypertrophic, keloids, ice pick scars, depressed fibrotic and atrophic macules, perifollicular elastolysis). Post-inflammatory hyperpigmentation is commonly seen in pigmented skin.

**GRADING OF ACNE**

Grading the severity of acne helps to determine the appropriate treatment. Many grading systems exist, but the Leeds revised acne grading system (a numerical pictorial grading system)

seems to be the most accurate, reproducible, and rapid (fig 1).  

As well as assessing the clinical aspects, it is also important to assess the psychological impact using tools such as the APSEA questionnaire (fig 2) or the Cardiff acne disability index.  

MANAGEMENT OF ACNE

Management should comprise safe treatment, reduction of the psychological burden through emotional and social support, and clarifying popular misconceptions about the disease.

Treatment should start as early as possible to minimise the risks of scarring or adverse psychological effects. It should be aimed at reducing non-inflammatory lesions that may be precursors to inflammatory lesions, improving existing inflammation, and lowering the P. acnes population. Treatment must be tailored to the individual patient, the type of acne, its severity, the patient’s ability to use the treatment, and their psychological state. It is very important to emphasise to the patient from the outset that the treatment of acne is a long-term affair. Advice on the use of cosmetics, moisturisers, sunscreens, and hair gels may be appropriate, as some formulations are greasy and could exacerbate existing acne or even cause acne-type lesions.

Treatment of mild acne

Topical preparations are the mainstay therapy, and their main action is the prevention of new lesions. Their effect is slow and treatment should be maintained to prevent recurrence. Topical agents are active only where and when they are applied, and should therefore be applied daily to all areas of the skin prone to acne. Maintenance therapy is crucial to prevent recurrence.

The topical agents available are benzoyl peroxide, antibiotics, azelaic acid, and retinoids.

Benzoyl peroxide is bactericidal for P. acnes and improves both inflammatory and non-inflammatory lesions. It is an oxidising agent that works by introducing oxygen into follicles, which then kills P. acnes. Because of this mechanism of action, P. acnes never develops resistance to benzoyl peroxide, however there can be adverse side effects such as irritant dermatitis and bleaching of hair, clothes, and linen.

Topical antibiotics such as clindamycin, tetracycline, and erythromycin are bacteriostatic for P. acnes and are effective for mild to moderate inflammatory acne.  

Topical retinoids such as tretinoin and adapalene correct abnormalities in follicular keratinocytes. They are effective in both the treatment of inflammatory lesions and in the prevention of the formation of comedones. They may also reduce inflammation by interfering with the interaction between Toll-like receptor 2 and external products of P. acnes on the surface of antigen-presenting cells. In addition, topical retinoids improve the penetration of other topical medications and may also help to improve the hyperpigmentation that is left in dark skin types after the resolution of inflammatory lesions. The maximum therapeutic response to topical retinoids occurs over about 12 weeks. They may produce local irritation, increased sensitivity to sunlight, and exacerbation of inflammatory lesions.

Combined agents such as erythromycin/zinc, erythromycin/tretinoin, erythromycin/sotretinoin, erythromycin/benzoyl peroxide, and clindamycin/benzoyl peroxide are increasingly being used and are useful in reducing the development of antibacterial resistance in P. acnes.

Most of these topical preparations are available in a variety of strengths and delivery systems. Drying agents (gels, washes, and solutions) are particularly suited to oily skin, whereas creams, lotions, and ointments are more suited to patients with dry, easily irritated skin.

TREATMENT OF MODERATE ACNE

Oral antibiotics are the standard treatment for moderate acne and for cases where topical combinations are not tolerated or are ineffective. They have been shown to reduce the number of P. acnes. In addition to interfering with the growth and metabolism of propionobacteria, antibiotics have an anti-inflammatory activity by reducing and inhibiting cytokine production, affecting macrophage function, and inhibiting neutrophil chemotaxis. The main systemic antibiotics used are erythromycin and different types of tetracyclines. They have a long history of verified efficacy in the management of inflammatory acne. Erythromycin (macrolide) should be reserved for cases where tetracyclines are not tolerated or are contraindicated: for example in pregnancy, when breast feeding, and in children below the age of 8–12 years.

First generation tetracyclines (tetracycline hydrochloride, oxytetracycline) or second generation tetracyclines (doxycycline, lymecycline, or minocycline) should be considered as first line oral antibiotic therapy. Tetracycline is inexpensive and is often effective in previously untreated cases, however gastrointestinal side effects and the need to take it on an empty stomach are disadvantageous.

One advantage of the second generation of tetracyclines relates to improved absorption that is unaffected by food. This may improve compliance when second generation tetracyclines are used, particularly for adolescents.

![Figure 1](image1.png) Photographs illustrating different grades of acne (adapted from O’Brien). (A) Mild acne (grade 2). Numerous comedones and a few pustules. (B) Moderate acne (grade 7). Numerous comedones and small inflammatory papules, numerous pustules. (C) Severe acne (grade 12). Numerous comedones, deeper papules and pustules, deep and large lesions, presence of cysts and abscesses.
Questions 1-6: tick the most appropriate answer to each question

In the past week:
1. Worrying thoughts have gone through my mind
   a) A great deal of time
   b) A lot of time
   c) From time to time, not often
   d) Only occasionally
2. I can still feel at ease and relaxed
   a) Definitely
   b) Usually
   c) Not often
   d) Not at all
3. I feel restless, as I have to be on the move
   a) Very much indeed
   b) Quite a lot
   c) Not very much
   d) Not at all

At this moment:
4. I like what I look like in photographs
   a) Not at all
   b) Sometimes
   c) Very often
   d) Nearly all the time
5. I wish I looked better
   a) Not at all
   b) Sometimes
   c) Very often
   d) Nearly all the time
6. On the whole I am satisfied with myself
   a) Strongly disagree
   b) Disagree
   c) Agree
   d) Strongly agree

Questions 7-15: read the following questions carefully and put a line at the point that most accurately represents how you feel.

7. I still enjoy the things I used to do
   Never 0 10 all the time
8. I am more irritable than usual
   Never 0 10 all the time
9. I feel that I am useful and needed
   Never 0 10 all the time

How has your skin condition limited the following activities or made them more difficult or awkward or less enjoyable since you have had acne?

10. Going shopping
    Not at all 0 10 all the time
11. Going out socially to meet friends from the home
    Not at all 0 10 all the time
12. Going away for week ends, holidays and outings
    Not at all 0 10 all the time
13. Eating out
    Not at all 0 10 all the time
14. Using public changing rooms, swimming pools
    Not at all 0 10 all the time
15. Do you think your appearance will interfere with your chances of future employment?
    Strongly disagree 0 10 Strongly agree
Doxycline is cleared by the liver, allowing this treatment to be used in patients with renal impairment. Co-trimoxazole and trimethoprim have been used as third line agents in the treatment of acne when other systemic antibiotics are contraindicated or there is verified resistance to other agents.

Table 1 outlines the optimum dose regimen, expense, incidence of bacterial resistance, and potential adverse effects. It is recommended to continue treatment for up to three months. If little response is seen after six weeks, the addition of a topical non-antibiotic medication or a switch to an alternative oral antibiotic should be considered. After control of acne is achieved and maintained for at least two months, a reduction in the dose can be attempted. Eventual withdrawal is the goal, followed by long term topical therapy.

Resistance to antibiotics is a problem, and a large contributory factor has been their widespread inappropriate use (such as inadequate potency, inadequate duration of treatment, and/or poor compliance). This may cause therapeutic failure in some patients. However, as a result of a change in prescription policy the level of resistance has recently fallen. Guidelines for optimising oral antibiotic use and preventing the emergence of resistant strains is given in Box 1.

If resistance to tetracycline is suspected, switching to minocycline is recommended, as resistance to it is rare.

**Hormonal therapy**

This can be very effective in women irrespective of their serum androgen levels. Oral contraceptives may decrease free testosterone level, and the oestrogen component may decrease the production of androgens by suppressing the secretion of pituitary gonadotrophins. The adverse effects of oral contraceptives include nausea, breakthrough bleeding, weight gain, and breast tenderness. Available scientific evidence does not support the hypothesis that antibiotics lower the contraceptive efficacy of oral contraceptives. Anti-androgen therapy may be of use to treat acne in women, particularly those with deep seated nodules of the lower face and neck. A combination of cyproterone acetate and ethinyl oestradiol (Dianette) is often effective, but its effect may be delayed for three to six months. Side effects of cyproterone include menstrual abnormalities, breast tenderness, nausea, vomiting, fluid retention, headache, and melasma. Pregnancy should be avoided during therapy with cyproterone, because of potential for feminisation of the male fetus. Spironolactone in doses of 50–100 mg twice daily seems to reduce sebum production and improves acne. It acts as an androgen receptor blocker and inhibits 5α-reductase. There is a theoretical risk of carcinogenicity and is therefore used only rarely. The starting dose should be around 25–50 mg daily and, provided the patient does not experience breast tenderness or headaches, can be increased to the maximum of 200 mg. It can be combined with the oral contraceptive in sexually active women to avoid the risk of pregnancy and feminisation of the fetus.

**Treatment of severe acne**

Patients with severe acne that does not clear with combined oral and topical therapy are considered for treatment with oral isotretinoin. Isotretinoin is a member of the retinoid class of compounds related to retinol (vitamin A). It is the only treatment that has an effect on all four of the major factors involved in the pathogenesis of acne: decrease the production of sebum, reduce bacterial numbers, decrease inflammation, and decrease the secretion of pituitary gonadotrophins. The adverse effects include menstrual abnormalities, breast tenderness, nausea, vomiting, fluid retention, headache, and melasma.

---

**Box 1 Recommendations to limit antibacterial resistance of *P* acnes (adapted from Simpson, Tan, Cunliffe)**

- Avoid antibiotics if non-antibiotic agents such as benzoyl peroxide or retinoids are effective.
- Only continue antibiotics until the doctor and the patient agree there is no further improvement.
- Prescribe antibiotics for a maximum of six months.
- Use the same antibiotics if relapse occurs.
- Give antibiotics for a minimum of two months before changing because of poor therapeutic response.
- Avoid concomitant use of oral and topical antibiotics with chemically dissimilar properties to decrease development of resistance to both agents.
- Use short intervening courses (5–7 days) of benzoyl peroxide to reduce/eliminate selected resistant propionobacteria.
- Use benzoyl peroxide in combination with topical and oral antibiotics. Use systemic isotretinoin if several antibiotics have been tried without success.
- Culture *P* acnes for antibiotic sensitivities.
- Educate patients on the importance of good adherence to the prescribed regimen and the importance of limiting exposure to antibiotics.

predisposing factors such as obesity, alcoholism, diabetes, or familial hyperlipidaemia. Pre-treatment levels are not necessarily predictive of increased levels of triglycerides and cholesterol during retinoid treatment. The high levels can be managed at least partially by an appropriate diet and lipid lowering drugs.

Severe potential side effects such as depression and suicide have been reported to occur within the first two months of treatment, however this was not seen in population based studies. The risk of inducing depression should be balanced with the psychological benefit of effective treatment. Pseudotumour cerebri and benign intracranial hypertension with papilloedema is a rare complication of isotretinoin therapy and has been reported when combined with oral tetracyclines.

The drug is only to be prescribed by dermatologists and a pregnancy prevention programme should be followed. Signed consent should be obtained confirming that the patient knows not to get pregnant during therapy and for four weeks afterwards. A pre-treatment pregnancy test is required and monthly pregnancy testing throughout treatment is a recommended option. Treatment should be started on the second or third day of menstruation and reliable contraception should be used where necessary.

Isotretinoin is metabolised by cytochrome P450 enzymes, and thus it may have potential interaction with other drugs (see table 2).

Physical, rather than pharmacological, forms of therapy that result in rapid relief of acne include the removal of comedones and the direct injection of corticosteroids into inflamed cysts. Other modalities that are currently being evaluated include the application of topical ALA (alpha-levulnic acid) followed by exposure to broadband UV light, and the N-Lite laser.

Atrophic scarring can be treated with laser resurfacing, dermal collagen injection, or antiligual fat implants. Hypertrophic scarring can be treated by chemical peels, microdermabrasion, topical corticosteroid cream, intraleisional triamcinolone injection, excision, cryotherapy, or application of silicone gels.

**CONCLUSIONS**

Acne is an extremely common skin condition, and despite not directly endangering life it can have a devastating physical and psychological effect on the lives of vulnerable adolescents. Effective and safe treatments for acne are available, yet many do not consider it a problem worth treating. Treatment of acne should be started early to prevent scarring, and the most effective agent with the minimum risk of adverse effects should be chosen. There is widespread misjudgment of the condition in both the medical profession and the public. Dispelling misconceptions about acne, its causes, and availability and efficacy of treatment must start from medical school to prevent the continuing perpetration of misinformation throughout the community. The failure of patients to take medicine in a way that would lead to therapeutic benefit is an important problem. Health education should ensure that patients have accurate information of the causes of acne and also that they have realistic expectations about the time frame and probable results of treatment. Better education and care given by medical staff and other professionals to patients is central to concordance, because it will allow them to treat themselves more effectively.

**MULTIPLE CHOICE QUESTIONS; ANSWERS AT THE END OF THE REFERENCES**

1. Acne is caused by

   (A) Propionobacterium acnes
   (B) Excessive intake of fatty food
   (C) Poor hygiene
   (D) Corticosteroids

**Box 2 Indication for the use of oral isotretinoin**

**Ideal for**
- Severe acne
- Patients in carefully selected cases with the combination of the following:
  - Moderate acne unresponsive to conventional therapy
  - Moderate acne relapsing after conventional therapy
  - Acne scarring
  - Psychological effects resulting from acne and scarring
  - Unusual form of acne

**Key references**

2. Comedones are produced by
   (A) Changed keratinisation in hair follicle
   (B) Insipidisation of keratin
   (C) Distension of pilosebaceous unit
   (D) Colonisation by propionibacterium.

3. Severe acne consist of
   (A) Numerous comedones
   (B) Small superficial papules
   (C) Cysts
   (D) Abscess

4. Treatment of acne should be aimed at reducing
   (A) non-inflammatory lesions
   (B) inflammatory lesions
   (C) P. acne population
   (D) Psychological burden

5. Oral isotretinoin
   (A) is the only treatment that may lead to permanent remission of acne.
   (B) is not effective against all major factors involved in the pathogenesis of acne.
   (C) induced mucosal dryness is not reversible on cessation of treatment.
   (D) induced suicidal tendency should be balanced with the psychological benefit of treatment.
